CONTRIBUTIONS IN SCIENCE

CAMPONOTUS USTUS FOREL AND TWO SIMILAR NEW SPECIES FROM PUERTO RICO (HYMENOPTERA: FORMICIDAE)

ROY R. SNELLING AND JUAN A. TORRES
The scientific publications of the Natural History Museum of Los Angeles County have been issued at irregular intervals in three major series; the issues in each series are numbered individually, and numbers run consecutively, regardless of the subject matter.

- Contributions in Science, a miscellaneous series of technical papers describing original research in the life and earth sciences.
- Science Bulletin, a miscellaneous series of monographs describing original research in the life and earth sciences. This series was discontinued in 1978 with the issue of Numbers 29 and 30; monographs are now published by the Museum in Contributions in Science.
- Science Series, long articles and collections of papers on natural history topics.

Copies of the publications in these series are sold through the Museum Book Shop. A catalog is available on request.

The Museum also publishes Technical Reports, a miscellaneous series containing information relative to scholarly inquiry and collections but not reporting the results of original research. Issue is authorized by the Museum's Scientific Publications Committee; however, manuscripts do not receive anonymous peer review. Individual Technical Reports may be obtained from the relevant Section of the Museum.

CAMPONOTUS USTUS FOREL AND TWO SIMILAR NEW SPECIES FROM PUERTO RICO (HYMENOPTERA: FORMICIDAE)

ROY R. SNELLING¹ AND JUAN A. TORRES²

ABSTRACT. Although Camponotus ustus Forel, originally described from St. Thomas, now a part of the American Virgin Islands, has been long considered common in Puerto Rico, we found that such specimens are misidentified and actually represent two distinct species, both previously undescribed. These are described herein as C. kaua and C. taino. Based on the types and additional material from Mona Island, we have redescribed C. ustus. The following new synonymy is proposed: C. ustus = C. ubysses Forel = C. furnissi Wheeler and Mann = C. sublaetus Wheeler and Mann = C. depolitus Wheeler = C. larvigerus Wheeler and Mann = C. larvigerus maculifrons Menozzi. One purported Colombian variety, arbuscus Forel, is tentatively elevated to species. All three species are illustrated, and a key is provided, in English and Spanish, for the separation of the Camponotus of Puerto Rico and the Virgin Islands.

RESUMEN. Aunque Camponotus ustus Forel, originalmente descrita de la Isla de St. Thomas, se ha considerado común en Puerto Rico, hemos encontrado que estos especímenes habían sido identificados incorrectamente y actualmente representan dos especies diferentes y sin describir. Estas nuevas especies son descritas aquí como C. kaua y C. taino. Basado en los tipos de C. ustus y material adicional de la Isla de Mona, hemos redescrito esta especie; las subespecies de C. ustus de La Española (ubysses Forel, furnissi Wheeler y Mann, sublaetus Wheeler y Mann, y depolitus Wheeler) son tratadas como sinónimos. Una variedad presumiblemente Colombiana, arbuscus Forel, es tentativamente elevada a especie. Las tres especies son ilustradas y una clave es presentada, en inglés y español, para identificar las especies de Camponotus de Puerto Rico y las Isla Virgenes.

INTRODUCTION

Wheeler (1908) recorded specimens from several Puerto Rican localities as Camponotus ustus, and subsequent researchers (e.g., Smith 1937) have been content to accept that identification. We examined many of the specimens seen by Wheeler, Smith, and others; it quickly became apparent that we were dealing with a mixed lot that actually consisted of two species. In order to determine which was the true C. ustus, described from St. Thomas, Virgin Islands, RRS examined the syntypic series in the Museum d’Histoire Naturelle, Geneva (MHNG). Despite the unusually poor condition of the few specimens available, it became clear that neither of the Puerto species was conspecific with those syntypes. We were further able to determine, after examining type material of similar-appearing taxa described from other Greater Antillean islands, that neither had been previously described from elsewhere and that both appear to be Puerto Rico Bank endemics.

¹ Entomology Section, Emeritus, Natural History Museum of Los Angeles County, 900 Exposition Blvd., Los Angeles, CA 90007.
² Departamento de Biología, Universidad de Puerto Rico, P.O. Box 23360, San Juan, PR 00931-3360, and Instituto Internacional de Dasyonemia Tropical, USDA Forest Service, P.O. Box 25000, Rio Piedras, PR 00928-2500.

In order that the names might be available for use by other researchers, in advance of our general treatment of the Puerto Rican ants, we here recharacterize C. ustus and describe as new the two Puerto Rican species.

SPECIMENS EXAMINED

In addition to the abundant Puerto Rican material deposited in the Los Angeles County Museum of Natural History (LACM), we have studied important syntypic and other specimens in the collections of the Museum of Comparative Zoology (MCZ), the Museum d’Histoire Naturelle, Geneva (MHNG), and the National Museum of Natural History (USNM).

TERMINOLOGY

The morphological terminology used below is consistent with most recent literature on ant systematics (e.g., Bolton 1994). We differ from Bolton in some respects. For example, we consider the ant head to be hypognathous; therefore, the vertex ("occupit" of some authors) is dorsal, rather than "posterior" and the mandibles are ventral, rather than "anterior." It follows, then, that the antennal sockets and frontal lobes are on the front of the head, not on the "dorsum." The following acronyms and special terms are used in the descriptions:

Cephalix Index (CI)—The ratio of head length
(HL) to head width (HW), as expressed by the formula: (HL/HW)(100).

Clupeal Apex—The lower, free margin of the clupeus.

Eye Length (EL)—The maximum diameter of the eye as measured in lateral view.

Head Length (HL)—The maximum length of the head, from the lower clupeal margin to the summit of the vertex, not including the mandibles.

Head Width (HW)—The maximum width of the head, in frontal view, exclusive of the compound eyes.

Intercellular Distance (IOD)—For gynes and males only: the shortest distance between the inner margins of the lateral (or posterior) ocelli.

Lower Head Width (LHW)—In frontal view, the width of the head at the level of the apparent mandibular insertions.

Malar Area—With the head in lateral view, that area that lies between the lower end of the compound eye and the base of the mandible.

Metasoma—The segments following the petiole are described as T1, T2, etc. (= tergum 1, tergum 2, etc.).

Minimum Ocular Diameter (MOD)—With the head in lateral view, the least diameter of the eye perpendicular to the eye length.

Ocellar Diameter (OD)—For gyves and males only: the transverse diameter of the anterior (or middle) ocellus with the head in full frontal view.

Ocellovertexal Distance (OVD)—For gyves and males only: with the head in full frontal view, the distance between the upper margins of the lateral (or posterior) ocelli and the dorsal margin of the vertex.

Ocular Index (OI)—The ratio of eye length to head length, as expressed by the formula: (EL/HL)(100).

Oculomandibular Distance (OMD)—With the head in lateral view, the shortest length of the malar area.

Oculomandibular ratio (OMR)—The ratio of eye length to the oculomandibular distance, as expressed by the formula: (EL/OMD)(100).

Scape Index (SI)—The ratio of scape length to head length, as expressed by the formula: (SL/HL)(100).

Scape Length (SL)—The greatest length of the antennal scape, excluding the basal condyle.

Total Length (TL)—The sum of HL + WL = length of metasoma.

Weber's Length (WL)—The diagonal length of the mesosoma, from the anterior margin of the pronotum (exclusive of pronotal neck) to the propodeal valve.

In the descriptions below, the appropriate measurement or ratio within parentheses is that of the type specimen. The diagnoses are intended to distinguish among the species of Camponotus found in Puerto Rico and other islands of the Puerto Rico Bank; they are not diagnostic within the genus as a whole.

Camponotus usitais Forel

Figures 1–6

Camponotus usitais var. ulysseis Forel 1907:11; soldier, gyne, male. Lago Assuei, Dominican Republic; syntypes MCZ, MHNG, examined. NEW SYNONYM.

Camponotus larigera Wheeler and Mann 1914: 52; soldier, worker, gyne. Grande Rivière, Haiti; syntypes MCZ, examined. NEW SYNONYM.

Camponotus larigera var. maculifrons Menozzi, in Menozzi and Russo 1930:167; major, worker. Pueblo Viejo, Dominican Republic. Not examined. NEW SYNONYM.

Camponotus usitais var. furnissi Wheeler and Mann 1914:55; soldier, worker, gyne. Petionville, Haiti; syntypes MCZ, examined. NEW SYNONYM.

Camponotus usitais var. sublaetus Wheeler and Mann 1914:55; soldier, worker, male. Diquini, Haiti; syntypes MCZ, examined. NEW SYNONYM.

Camponotus usitais var. depolitis Wheeler 1936: 205; soldier, worker, male. Sánchez, Dominican Republic; syntypes MCZ, examined.

DISCUSSION. The subgeneric placement of C. usitais has been uncertain. Forel (1879) originally thought that it might be related to C. fulidus, currently placed in Tanaemyrmex. Emery (1920), however, removed it to Pseudocolobopsis, where it remained until Kempf (1972) returned it to Tanaemyrmex. The specimens that Emery had available to him were, however, misidentified individuals of the species described below as C. kaura; in the absence of a discussion, it is unclear why Kempf (1972) returned C. usitais to Tanaemyrmex. While the limits of the various subgenera of New World Camponotus are somewhat vague, this species does seem to accord better with the features of Tanaemyrmex than with those of Pseudocolobopsis.

Features that C. usitais shares with Tanaemyrmex, but not with Pseudocolobopsis, include the following (based on worker caste unless otherwise noted): (1) Head margins of major worker strongly convergent below rather than parallel or subparallel, and differing from both the media and minor workers in which the head margins are usually parallel or nearly so. (2) Head shape of gyne similar to that of media worker rather than that of major worker. (3) Frontal carinae relatively close to one another and far removed from inner eye margins. (4) Clypeal apex relatively thick and with broadly triangular bevelled area above margin; margin without median tooth. (5) Mandible with 7, rather than 6, teeth. (6) Media workers present and clearly transitional between majors and minors. (7) Profile of propodeum long and low, without differentiated dorsal and posterior faces.

The two new species described below, on the other hand, differ from Tanaemyrmex in each of the
features listed above and are more like species of *Pseudocolobopsis*. One of these species, *C. kaura*, is somewhat transitional in some features. The head shape of the major worker, while similar to that of the gyne, is not quite typical for *Pseudocolobopsis*, since the margins are a little more convergent below than is usual in that group. The distal portion of the antennal scape is not abruptly broadened, a common feature of *Pseudocolobopsis* species. Poorly defined media workers are present, a subcaste that is often, but not always, absent in *Pseudocolobopsis*.

In addition to the synonyms listed above, Forel (1902) described *C. ustus* var. *arhuacus* from San Antonio, Colombia. The type, and only known specimen, is a minor worker and is in the Forel collection at the MHNG. This specimen has been examined, and we conclude that it is not conspecific with *C. ustus*. When compared with minors of *C. ustus* in the same size range (HW ca. 1.0 mm) the
head of the var. arbuacus type is proportionately broader (CI 81 versus CI ca. 77–78); in profile, the frontal area is abruptly elevated above the base of the clypeus in C. ustus but gradually sloping in the var. arbuacus type. In the latter, along the side of the head, from the base of the mandible to a point above the lower eye margin, there are conspicuous erect setae. In C. ustus, on the other hand, there usually are no such setae, but when present they are limited to one or two situated near the base of the mandible. The type of var. arbuacus also has numerous short erect setae on the clypeus in addition to about 6 long erect setae. Six to eight long erect setae are also present in C. ustus, but there are no very short setae on the clypeal disc.

In general, the head of the var. arbuacus type is much hairier than that of similar-sized individuals of C. ustus. Our view at present is that var. arbuacus should be considered a separate species, C. arbuacus (NEW STATUS), in the subgenus Tanaemyrmex. It may ultimately prove to be synonymous with some other Colombian species. In addition, it should be noted that all other known forms assigned to C. ustus are limited to the Greater Antilles, far removed from the one known locality for C. arbuacus.

Wheeler and Mann (1914) briefly discussed a major worker specimen from Port-au-Prince, Haiti, received from Forel and, perhaps, identified by him as C. ustus. This individual was not available to us but is evidently notably hairy and not at all similar either to C. ustus syntypes or to other material we have studied. Whatever species this may be, it would seem to be something other than C. ustus. In fact, it is possible that this could be the species described below as C. taino, although we have seen no specimens of C. taino from Hispaniola.

The remaining forms described as varieties of C. ustus, all from Hispaniola, are based on trivial differences in color, sculpture, and pilosity. There are, moreover, no consistencies among the material we have been able to examine, with some colony samples including two or more of these varieties. Under the circumstances, any attempt to segregate these seems futile, and all are here reduced to synonymy.

Finally, we have examined syntypes of C. larvigerus, described by Wheeler and Mann (1914) from Grand Rivière, Haiti. Although they compared it to the very different C. ramulorum Wheeler, no comparison was made to C. ustus. We have made that comparison and conclude that the two are conspecific. We have not seen Menozzi’s var. maculifrons, but the scanty description suggests that this, too, is nothing more than a minor color variant of a species that, like so many Camponotus, exhibits considerable variability in color.

In addition to the various syntypes from Hispaniola, we have collected C. ustus at a bona fide Puerto Rican locality: Mona Island, lying between Hispániola and Puerto Rico.

The following redescription of the female castes of C. ustus is based primarily on our material collected at Mona Island. These specimens have been compared with the type material and, in our opinion, are conspecific. Vouchers are deposited in the BMNH, LACM, MCZC, and MHNG.

**DIAGNOSIS.** Female castes. Head margins (major) distinctly convergent below or (media, minor, gyne) subparallel, without standing setae between mandible and dorsolateral angle; antennal scape with sparse erect setae along shaft; free clypeal margin transverse, thick and with median, broadly triangular beveled area; mandible with seven teeth (sometimes obscurely so). Male. See Discussion below.

**DESCRIPTION.** **Major worker, measurements (mm) (n = 30):** HW 1.64–2.26 (2.04); HL 1.95–2.46 (2.14); SL 1.95–2.05 (–); WL 2.6–3.1 (–); TL 7.5–8.7. **Ratios and indices:** CI 105–119 (105); SI 83–103 (–); OI 20–25 (24); OMR 48–60 (56). Note: due to the poor condition of the one major worker in the syntypic series some measurements were not possible, hence the (–).

**Head** (Fig. 1) slightly longer than wide in frontal view, sides gently curved and strongly convergent below, LHW about 0.68 × HW; vertex concave between distinct dorsolateral lobes. Eyes relatively small and, in frontal view, outer margins short of lateral head margins by more than minimum diameter of scape. Frontal lobes narrow, greatest intercarinal distance about 0.32 × HW; upper intercarinal distance about 0.8 × greatest intercarinal distance. Clypeal midline weakly subangulate for most of its length, terminating below in broadly triangular median beveled area (Fig. 6); free (ventral) margin thick, straight between obtuse lateral angles. Antennal scape moderately broadened distad, apex well beyond summit of dorsolateral lobes; mandible with 7 teeth.

Front of head shiny, surfaces coarsely tessellate, clypeus and lower malar area less shiny, more finely tessellate; entire front of head sparsely and minutely punctate, clypeus with few fine punctures but with coarser setigerous punctures. Mandible about as shiny as clypeus, with obscure minute punctures and scattered coarser setigerous punctures. Posterior surface of head shiner between sparse to scattered minute punctures and coarser piligerous punctures.

Side of head (including malar area) without erect setae; eyes bare; vertex and upper frons with 3–5 erect setae on each side, outermost shortest; frontal lobes with 5 long erect setae along each margin and shorter submedian dorsal pair. Clypeus with usual basil seta pair and 4–6 similar discal hairs; usual fringe of widely spaced long curved setae along free margin; hypostomal area with 2–4 short erect setae. Distal two-thirds of scape shaft with variable number of short erect setae that are shorter than distance between them. **Mesosoma** (Fig. 4) robust, dorsum moderately convex in profile, metanotal depression absent; propodeum strongly curved and without definite posterior declivity. Pronotal dorsum about 1.1× as
wide as long and almost 4\(\times\) as wide as propodeum at summit of "declivity." Profemur about 3.5\(\times\) as long as deep.

Prontum with 4–6 long erect setae on each side that are weakly inclined forward, longest about 0.9 \(\times\) MOD; mesonotum with (usually) 3 seta pairs, middle pair longest; summit of propodeal "declivity" with 4 or 5 long setae. Profemur with 1–3 long setae on posterior face and about 6 well-spaced, short setae along ventral margin, longest about 0.20 \(\times\) depth of femur; meso- and metafemora each with variable number of ventral setae on basal one-fourth to one-third; tibiae without erect or suberect setae; meso- and metatibiae without row of graduated bristles along flexor surface.

_Petiole scale_ thin-cuneate in profile, summit acute; summit, in posterior view, broadly and evenly convex; summit with 3–4 long setae on each side, longest at least subequal to longest pronotal setae.

_Gaster_ moderately shiny, weakly transversely lineolate. T1 with 2 or 3 weakly defined rows of long discal setae in addition to marginal row; longest setae at summit of basal declivity longer than MOD; each following tergum with 1–3 ill-defined transverse rows of long setae.

_Color_ yellowish to brownish or reddish yellow, usually with lower face and frons conspicuously darker; mesosoma with varying degrees of infuscation; terga more or less brown banded.

_Media and minor workers, measurements (mm)_(n = 45): HW 1.07–1.41; HL 1.49–1.80; SL 1.79–1.96; WL 2.3–2.7; TL 6.2–7.7. Ratios and indices: CI 127–141; SI 109–122; OI 27–28; OMR 65–71. Generally similar to major workers, but more slender and with more elongate and parallel-sided heads that lack defined dorsolateral lobes (Fig. 2).

_Female, measurements (mm)_(n = 6): HW 1.58–1.86; HL 1.84–2.12; SL 1.68–1.90; WL 3.4–3.8; TL 10.1–10.7. Ratios and indices: CI 114–119; SI 87–90; OI 29–32; OMR 83–91.

_Head_ (Fig. 3) margins less convergent below than in major worker, LTH about 0.74 \(\times\) HW; vertex weakly convex and without defined dorsolateral lobes. Eyes large and extending slightly beyond head margins in frontal view; ocelli small, IOD about 3 \(\times\) OD; OVD (frontal view) about 2.5 \(\times\) OD. Scape surpassing vertex margin by about 0.3 \(\times\) SL. Sculpture and pilosity about as described above for major.

_Mesosoma_ (Fig. 5) normal-shaped for alate female. Propodeum with short dorsal face, broadly rounded into declivity and with several (4–6) long setae slightly above middle of declivity. Legs as described above.

_Petiole and gaster_ about as described above.

_Male: _see Discussion below._

**DISCUSSION.** Males of the 3 species treated here are similar: all are yellowish to brownish yellow, often with limited darker brownish areas on the head and mesosoma. They are similar in size, about 4.5–5.5 mm long. The smallest of the 3 species is _C. taino_, in which males are seldom over 4.6 mm long, but some individuals up to 4.9 mm long have been seen; HW usually falls between 0.69–0.73 mm and occasionally reaches 0.76 mm. Males of the 2 remaining species, _C. kaura_ and _C. ustus_, are usually about 3.5–5.6 mm long, but with some individuals above and below that range. In _C. ustus_, HW ranges between 0.88 and 0.93 mm; too few are available for a trend to be clear, but HW is usually over 0.90 mm. Males of _C. kaura_ are a little smaller, with a HW ranging between 0.78 and 0.91 mm, and in over 90% of the 54 males measured it exceeded 0.80 mm, with over 70% falling between 0.82 and 0.91 mm.

The ocelli of _C. kaura_ males are generally larger, and the IOD ranges between 1.5–2.5 \(\times\) OD; in most examples, it is 2.2 or less. In both _C. ustus_ and _C. taino_, the ocelli are smaller, and the IOD is 2.3–2.6 \(\times\) OD, usually about 2.5 \(\times\) OD.

Pilosity of the antenntal scape is consistently different between the 3 species. In _C. kaura_, it consists exclusively of fine, fully appressed pubescence, except for several long, suberect distal setae. The scapal pubescence of _C. taino_, in contrast, is abundant, coarse, and subdecumbent to suberect; the setae are quite short, less than 0.025 mm long. _Camponotus ustus_ is also provided with an abundance of similar short setae, but in addition there are scattered fine suberect setae that are about 0.08 mm long.

The metatibiae reflect similar differences: setae are fine and fully appressed in _C. kaura_, relatively coarse and subdecumbent to suberect and uniformly short in _C. taino_, and, finally, similar to _C. taino_, but with additional scattered longer setae in _C. ustus._

**Camponotus kaura**

_Snelling and Torres, new species_

_Figures 7–12_

**DIAGNOSIS.** Female castes. Head margins, in frontal view, subparallel and without standing setae between mandible base and dorsolateral angle; antenntal scape without standing setae along shaft; free clypeal margin transverse, thin, and without median beveled area above margin; mandible with 6 teeth. _Male:_ See Discussion under _C. ustus._

**DESCRIPTION.** _Major worker, measurements (mm)_(n = 53): HW 1.88–2.16 (2.16); HL 2.10–2.48 (2.44); SL 1.45–1.66 (1.66); WL 2.5–2.9 (2.9); TL 7.5–10.5 (10.5). Ratios and indices: CI 105–123 (113); SI 67–72 (68); OI 20–22 (20); OMR 45–50 (50).

_Head_ (Fig. 7) longer than wide in frontal view, sides straight or nearly so, weakly converging below, HW about 0.8 \(\times\) UHW; dorsolateral lobes distinct and margin between them deeply concave. Eyes large and flat, their outer margins failing to attain lateral head margins by less than minimum

Diameter of antennal scape. Frontal lobes broad, greatest intercarinal distance about 0.4 × HW; upper intercarinal distance about 0.9 × greatest intercarinal distance. Clypeal midline subangular for most of its length; disc slightly depressed on either side above lower margin; free margin shallowly concave and with blunt median tooth (Fig. 12); in profile, evenly sloping to ventral margin.

Antennal scape distinctly widened distad, extending to, or nearly to, level of dorsolateral lobe. Mandible with 6 teeth.

Front of head slightly to moderately shiny, surfaces finely tessellate; entire front of head sparsely and minutely punctate, clypeus least obviously punctate; mandible moderately shiny between sparse fine punctures that become finer, closer, and
more elongate basad and along lower margin; short costae present distad at base of dentate margin. Posterior surface of head shiner, with sparse to scattered minute punctures and coarser, piligerous punctures.

Side of head (including malar area) in frontal view without erect setae; eyes bare; vertex and upper frons with several long setae on each side, outermost longest; frontal lobes with 3 long erect setae widely spaced along carinae. Clypeus with usual basal seta pair and 2 or 3 similar setae along each lateral margin; 4–8 short, erect submedian setae present; 4–6 long, slightly curved, flattened bristles present along ventral margin, extending over closed mandibles. Scape without erect setae. Hypostomal area with 0–4 short erect setae.

Mesosoma (Fig. 10) robust, dorsum moderately convex in profile, metanotal depression weak; posterior declivity weakly concave. Pronotal dorsum about 1.2× as wide as long and about 2.2× as wide as propodeum at summit of declivity. Profemur about 3× as long as deep.

Pronotum with about 10 long suberect to erect setae; longest about 0.4 × minimum eye diameter (MOD); mesonotum with (usually) 4 similar setae; summit of propodeal declivity with 1 pair of long, erect setae. Profemur with 2 or 3 widely spaced erect setae along ventral margin, longest no more than 0.5 × depth of femur; meso- and metabasal setae without erect setae along either dorsal or ventral margins; all femora with several setae at their apices; all tibiae without erect or suberect setae, but each with several bristles at apex; meso- and metabasal setae without row of graduated bristles on flexor surfaces.

Pettiole scale thin-cuneate in profile, summit narrowly rounded; summit, in posterior view, varying from weakly concave across middle one-half to weakly convex; summit with 2 or 3 erect setae on each side, longest subequal to longest pronotal setae.

Gaster moderately shiny, weakly transversely linalate. T1 with 2 long submedian suberect setae at summit and usual marginal row; following segments with transverse median band of wide spaced erect setae in addition to marginal row, setae progressively longer on succeeding segments; appressed pubescence of terga widely scattered and extremely short (<0.03 mm long).

Color basically yellow; areas of varying extent on the head may be darker reddish or even brownish; similarly, metasomal terga may be weakly brown-banded.

Media workers, measurements (mm) (n = 6): HW 1.29–1.70; HL 1.38–1.84; SL 1.17–1.35; WL 1.8–2.2; TL 5.8–6.7. Ratios and indices: CI 101–108; SI 74–89; OI 23–31; OMR 54–72.

Generally similar to major workers but head more quadrate and without pronounced dorsolateral lobes.

Minor workers, measurements (mm) (n = 45): HW 0.85–1.27; HL 1.09–1.56; SL 1.19–1.62; WL 1.6–2.4; TL 4.6–6.6. Ratios and indices: CI 117–138; SI 104–113; OI 27–33; OMR 62–90.

Distinctly more slender bodied and with more elongate and parallel-sided heads, vertex evenly convex in frontal view (Fig. 8); antennal scape clearly longer than head; free clypeal margin broadly convex.

Gyne, measurements (mm) (n = 11): HW 1.56–1.71; HL 1.78–1.94; SL 1.37–1.49; WL 3.0–3.4; TL 8.8–9.7. Ratios and indices: CI 111–117; SI 73–78; OI 28–33; OMR 79–97.

Head (Fig. 9) in frontal view less convergent below than in major worker, LHW about 0.75 × HW; vertex nearly straight across middle. Eyes large and extending slightly beyond head margins; EL about 0.8 × OMD; ocelli small, IOD about 4 × OD; OVD about 3 × OD (frontal view). Scape surpassing vertex by about 0.17 × SL. Sculpture and pilosity as described above for major.

Mesosoma (Fig. 11) normally shaped for alate female. Dorsal face of propodeum only slightly shorter than declivitous face, abruptly rounded on it and with 4–6 long setae near summit of declivity. Legs as described above.

Pettiole and gaster about as described above.

TYPE MATERIAL. Holotype major worker, PUERTO RICO: Caño Gorda, 0–20 m, vic. Guánica, 26 Oct. 1991 (Snelling, Torres, and Canals, RRS #1-14), ex dead wood of black mangrove (Avicennia germinans), deposited in LACM. Para­types: numerous workers, gynes, and males, same data, RRS #5's 91-14 to 91-17; workers, same data except from dead wood of Coccoloba (RRS #91-18); para­types in BMNH, LACM, MCZ, USNM.

ETYMOLOGY. The specific name is a Taino (Arawak) word for a forest dweller; it is to be treated as a noun in apposition.

DISCUSSION. In addition to the above paratype material from Puerto Rico, we have seen specimens of all castes from nearly 50 additional sites in Puerto Rico, as well as samples collected by RRS on Tortola and Guana Island, British Virgin Islands.

As noted above in the Discussion under C. ustus, we believe that this species is probably a member of the subgenus Pseudocolobopsis as that taxon is currently defined.

The material available is generally quite uniform in its features, the most obvious variation being in color. While the color is basically yellow or brownish yellow, the amount and intensity of infusion of the head of the majors is quite variable. In some individuals, the lower two-thirds of the head may be blackish, but more usually the lower portions of the head are distinctly brown and the remainder is somewhat reddish.

One major worker, from the type nest sample, is unusual in that the head, the longest of any measured, is disproportionately slender for the major subspace, with a CI of 123. This is the only major examined in which the CI exceeds 113.

This is by far the more common of the two species previously misidentified by Wheeler (1908) and...
all subsequent authors as *C. ustus*. It is readily sepa-
ated from *C. taino* by the smooth malar area and
lateral margins of the head, since both are devoid of
erect setae. This species is separable from true *C.
ustus* by the differences in head shape and clyp-
eal structure as noted in the key and figures. In
Puerto Rico, *C. ustus* is presently known only from
Mono Island.

**Camponotus taino**
Snelling and Torres, new species

Figures 13–16

*Camponotus ustus*: Wheeler, 1908:156. M. Smith,

**DIAGNOSIS. Female castes.** Head margins in
frontal view subparallel and provided with numer-
ous short erect setae; free clypeal margin concave
and with small median process, thin and without
triangular beveled area above margin; antennal
scape with numerous fully erect short and long
setae; mandible with 6 teeth. **Male.** See Discussion
under *C. ustus*.

**DESCRIPTION.** Major worker, measurements
(mm) (*n* = 25): HW 1.23–1.54 (1.35); HL 1.39–
1.68 (1.49); SL 0.97–1.09 (1.01); WL 1.8–2.3 (2.0);
TL 5.8–6.8 (6.3). **Ratios and indices:** CI 109–113
(110); SI 63–70 (68); OI 24–27 (26); OMR 54–66
(57).

**Head** (Fig. 13) longer than wide in frontal view,
sides straight or nearly so, weakly converging be-
low, LHW about 0.8 × HW; dorsolateral lobes
weak and margin between them weakly concave or
flat. Eyes large and flat, outer margins failing to
attain head margins by less than minimum scape
diameter. Frontal lobes broad, greatest intercarinal
distance almost 0.5 × HW; upper intercarinal dis-
tance subequal to intercarinal distance. Clypeal
midline weakly obtuse; free margin thin and slaw-
lowly concave between rounded lateral angles and
with small median tooth (Fig. 16). Antennal scape
surpassing vertex margin by about its apical width
or slightly less. Mandible with 6 teeth.

Front of head slightly to moderately shiny, sur-
faces finely tessellate; entire front and sides of head
with sparse fine setigerous punctures that become
closer in malar area adjacent to clypeus; clypeal
punctures finer and less distinct. Mandible shiny
between fine sparse setigerous punctures. Posterior
surface of head shiner, punctures coarser than on
malar area.

All surfaces of head with numerous short erect
setae and sparser, variably longer setae; usual long
setae of margins of frontal lobes and vertex present
but inconspicuous; mandible with many short erect
setae; scape shaft with numerous very short setae,
mostly on frontal and dorsal surfaces; eyes with
sparse very short setae.

**Mesosoma** (Fig. 15): Profile of pronotum and
mesonotum nearly flat; propodeum broadly round-
ed onto distinct declivitous face that is usually
slightly concave; metanotal depression absent.
Pronotal dorsum about 1.3× as wide as long and
about 3.5× as wide as propodeum at summit of
declivity. Profemur about 2.3 as long as deep.

Dorsum of mesosoma with numerous very short
to short erect setae; pronotum with 8–10 longer
erect setae that are only weakly inclined cephalad,
longest about 0.6 × MOD; mesonotum with 2 sim-
lar longer setae; propodeum, at summit of decliv-
ity, with 6–8 longer setae, longest subequal to
MOD. Profemur with sparse short and longer setae
along outer face and 6–8 longer well-spaced setae
along ventral margin; meso- and metanotum
and pleurae with sparse suberect, very short setae,
femora with scattered longer setae; meso- and metatibiae
with row of bristles along flexor surface.

**Pelta** scale thin-cuneate in profile, summit
acute; summit, in posterior view, straight or weakly
convex and with 3 or 4 long setae on either side,
longest distinctly shorter than longest pronotal se-
tae.

**Gaster** shiny, finely transversely lineolate. T1
with transverse band of 4–8 long setae at summit
of declivity, submedian pair longest; disc with
transverse band of shorter, widely spaced setae at
midlength in addition to usual marginal band; T2–
T4 with subbasal bands; all terga with sparse short
erec
t setae.

**Color** as described above for *C. kaura*, but
head commonly largely brownish.

**Minor workers, measurements** (mm) (*n* = 45):
HW 0.77–1.05; HL 0.95–1.19; SL 1.07–1.21; WL
1.4–1.7; TL 4.2–5.4. **Ratios and indices:** CI 112–
129; SI 100–111; OI 32–34; OMR 76–89. No
workers comparable to the *media workers of C.
kaura* have been seen. The minor workers are sim-
ilar to the major, but are more slender, with pro-
portionately longer antennal scapes; vertex evenly
convex in frontal view, shortest setae proportion-
ately shorter and less abundant (Fig. 14).

**Gyne, measurements** (mm) (*n* = 10): HW 1.23–
1.37; HL 1.41–1.57; SL 1.10–1.11; WL 2.4–2.8;
TL 6.8–8.1. **Ratios and indices:** CI 113–115; SI 71–
79; OI 33–47; OMR 96–104.

**Head** about as in major worker, but eyes larger,
extending slightly beyond head margins in frontal
view; EL about 0.8 × OMD; ocelli small, IOD
about 3 × OVD, OVD about 2.5 × OD. Scape sur-
passing vertex margin by about its apical width.

**Mesosoma** about as in *C. kaura* but dorum ad-
ditionally with numerous very short setae.

**Pelta** and **gaster** about as described for major.

**Male:** see Discussion under *C. kaura*.

**TYPE MATERIAL.** Holotype major worker,
PUERTO RICO: El Verde Field Station (Rio Gran-
de), 200 m, 25 July 1989 (Snelling & Torres, RRS
#89-28b), ex dead branch in tree, "Tabonuco" rain-
forest, in LACM. Paratypes: numerous workers with
same data, as well as additional workers col-
lected at same locality, 19 Feb. 1988 (T. Gush,
#TG-1050), in BMNH, LACM, MCZ, USNM.

**ETYMOLOGY.** This species is dedicated to the
Taino Arawak people, the original inhabitants of
Puerto Rico and adjacent islands at the time of the European arrival in the Western Hemisphere; the name is a masculine noun in apposition.

DISCUSSION. As noted above, in the discussion under C. ustus, the evidence supports placement of this species in the subgenus Pseudocolobopsis as that taxon is currently defined. 

As far as is currently known, C. taino is limited to Puerto Rico. In addition to the type material, we have seen specimens from a dozen additional Puerto Rican localities. This species appears to be the less common of the two Puerto Rican ants previously misidentified as C. ustus by Wheeler (1908) and all subsequent authors. The presence of numerous short, erect setae on the malar area and along the sides of the head will permit easy recognition of C. taino.

KEYS

Workers of the 3 species of Camponotus treated here may be separated by means of the following key, given in both English and Spanish language versions. This key is for the species of Camponotus known to occur in Puerto Rico and the Virgin Islands and does not include several similar-appearing yellowish species on Hispaniola, Cuba, and Jamaica.

CAMPONOTUS OF PUERTO RICO 
AND VIRGIN ISLANDS

1. Mesosoma, in profile, not deeply depressed at rear of mesonotum (Figs. 4, 10); color largely yellowish and gaster without pale spots ............................................. 2

- Mesosoma, in profile, deeply depressed at rear of mesonotum; head reddish, body reddish to blackish and gaster terga with sublateral pale spots ........................................... C. sexguttatus (Fabricius)

2(1). Workers dimorphic and head of female similar to that of major; in frontal view, head of major with sides nearly parallel (Figs. 7, 13); apical margin of clypeus thin and depressed (Figs. 12, 16) ........................................... 3

- Workers polymorphic and head of female similar to that of worker media; in frontal view, head of major distinctly narrowed below (Fig. 1); apical margin of clypeus thick and with triangular median beveled area (Fig. 6) ........................................... C. ustus Forel

3(2). In frontal view, numerous short, erect setae present along side of head from mandible base to dorsolateral angles of vertex (Fig. 13); eyes with very short, sparse erect setae ........................................... C. taino, n. sp.

- Side of head without erect setae (1 or 2 may be present near base of mandible) (Fig. 7); eyes without erect setae ........................................... C. kaura, n. sp.

CAMPONOTUS DE PUERTO RICO 
Y LAS ISLAS VIRGENES

1. Mesosoma, en perfil, no profundamente rebajado en la parte de atrás del mesonoto (Figs. 4, 10); color generalmente amarillento y el gaster sin manchas pálidas ............................... 2

- Mesosoma, en perfil, profundamente rebajado en la parte de atrás del mesonoto; cabeza rojiza, cuerpo de rojizo a negruzco y las tergas gastrales tienen manchas pálidas sublaterales ...................................... C. sexguttatus

2(1). Obreras dimórficas y la cabeza de la hembra similar a la de los mayores; visto frontalmente la cabeza de los mayores con los lados casi paralelos (Figs. 7, 13); margen apical del clípeo delgado y rebajado (Figs. 12, 16) 3

- Obreras polimórficas y la cabeza de la hembra similar a la de las obreras medianas; visto frontalmente la cabeza de los mayores distintamente estrecha abajo (Fig. 1); margen apical del clípeo grueso y con un área triangular angulada en la región medial (Fig. 6) .................................................. C. ustus

3(2). En vista frontal, pequeños y numerosos pelos erectos presentes a la larga de la cabeza desde la base de las mandíbulas a los ángulos dorsolaterales del vértex (Fig. 13); ojos con pelos erectos muy cortos y esparcidos ................................... C. taino

- Lados de la cabeza sin pelos erectos (uno a dos pueden estar presentes cerca de la base de la mandíbula) (Fig. 7); ojos sin pelos erectos ........................................... C. kaura

ACKNOWLEDGMENTS

We wish to particularly express our gratitude to Claude Besuchet (MHNG), Stefan Cover (MCZ), and Dave Smith (USNM) for their cooperation in making valuable syn- types available for study. Our thanks also go to Jack Longino and Gerardo Hernández for donating some Puerto Rican specimens and to Miguel Canals for assistance in field work at Guánica. Finally, we are indebted to Maribel Torres for assistance in the field at various localities. For the illustrations, we are indebted to Sharon Belkin. Special thanks are extended to Bob Hamton for his assistance in mounting long series of Camponotus specimens for this study. Partial support for our study of Puerto Rican ants was provided by a grant from Proyecto Atlantica, Universidad de Puerto Rico. Early drafts of the manuscript were reviewed and commented on by Brian V. Brown and Fred S. Truax; their efforts are deeply appreciated. Finally, final copy was greatly enhanced by the review comments of Jack Longino and Phil Ward, to whom we extend our thanks.
